## Module 3 Cheat Sheet: Apache Spark

Package/Method	Description	Code Examples
appName()	A name for your job to display on the cluster web UI.	Code Examples
cache()	An Apache Spark transformation often used on a DataFrame, data set, or RDD when you want to perform multiple actions. cache() caches the specified DataFrame, data set, or RDD in the memory of your cluster's workers. Since cache() is a transformation, the caching operation takes place only when a Spark action (for example, count(), show(), take(), or write()) is also used on the same DataFrame, data set, or RDD in a single action.	Code Examples
count()	Returns the number of elements with the specified value.	Code Examples
createTempView()	Creates a temporary view that can later be used to query the data. The only required parameter is the name of the view.	Code Examples
filter()	Returns an iterator where the items are filtered through a function to test if the item is accepted or not.	Code Examples
getOrCreate()	Get or instantiate a SparkContext and register it as a singleton object.	Code Examples
import	Used to make code from one module accessible in another. Python imports are crucial for a successful code structure. You may reuse code and keep your projects manageable by using imports effectively, which can increase your productivity.	Code Examples
len()	Returns the number of items in an object. When the	Code Examples

## de Example

```
1. from pyspark.sql import SparkSession
```

```
2. spark =
```

```
  SparkSession.builder.appName("MyApp").getOrCreate()
```

```
1. df = spark.read.csv("customer.csv")
```

```
2. df.cache()
```

```
1. count = df.count()
```

```
2. print(count)
```

```
1. df.createOrReplaceTempView("cust_tbl")
```

```
1. filtered_df = df.filter(df['age'] > 30)
```

```
1. spark = SparkSession.builder.getOrCreate()
```

```
1. from pyspark.sql import SparkSession
```

	object is a string, the <code>len()</code> function returns the number of characters in the string.
<code>map()</code>	Returns a map object (an iterator) of the results after applying the given function to each item of a given iterable (list, tuple, etc.)
<code>pip</code>	To ensure that requests will function, the pip program searches for the package in the Python Package Index (PyPI), resolves any dependencies, and installs everything in your current Python environment.
<code>pip install</code>	The <code>pip install &lt;package&gt;</code> command looks for the latest version of the package and installs it.
<code>print()</code>	Prints the specified message to the screen or other standard output device. The message can be a string or any other object; the object will be converted into a string before being written to the screen.
<code>printSchema()</code>	Used to print or display the schema of the DataFrame or data set in tree format along with the column name and data type. If you have a DataFrame or data set with a nested structure, it displays the schema in a nested tree format.
<code>sc.parallelize()</code>	Creates a parallelized collection. Distributes a local Python collection to form an RDD. Using <code>range</code> is recommended if the input represents a range for performance.
<code>select()</code>	Used to select one or multiple columns, nested columns, column by index, all columns from the list, by regular expression from a DataFrame. <code>select()</code> is a transformation function in Spark and returns a new DataFrame with the selected columns.
<code>show()</code>	Spark DataFrame <code>show()</code> is used to display the contents of the DataFrame in a table row and column format . By default, it shows only twenty rows, and the column values are truncated at twenty characters.
<code>spark.read.json</code>	Spark SQL can automatically infer the schema of a JSON data set and load it as a DataFrame. The <code>read.json()</code> function loads data from a directory of JSON files where each line of the files is a JSON object. Note that the file offered as a JSON file is not a typical JSON file

```
1. row_count = len(df.collect())
2. print(row_count)
```

```
1. rdd = df.rdd.map(lambda row: (row['name'],
2. row['age']))
```

```
1. pip list
```

```
1. pip install pyspark
```

```
1. print("Hello, PySpark!")
```

```
1. df.printSchema()
```

```
1. rdd = sc.parallelize([1, 2, 3, 4, 5])
```

```
1. selected_df = df.select('name', 'age')
```

```
1. df.show()
```

```
1. json_df = spark.read.json("customer.json")
```

`spark.sql()`

To issue any SQL query, use the `sql()` method on the `SparkSession` instance . All `spark.sql` queries executed in this manner return a `DataFrame` on which you may perform further Spark operations if required.

`time()`

Returns the current time in the number of seconds since the Unix Epoch.

```
1. result = spark.sql("SELECT name, age FROM cust_tbl WHERE  
    age > 30")  
2. result.show()
```

```
1. from pyspark.sql.functions import current_timestamp  
2. current_time =  
    df.select(current_timestamp().alias("current_time"))  
3. current_time.show()
```
